

# Technique for Mass Multiplication of Bethyloid Parasitoid for Control of Coconut Leaf Eating Caterpillar

Chandrika Mohan & Sumitha Nair S.

CPCRI (RS) Kayangulam, Krishnapuram - 690 533, Kerala

Coconut leaf eating caterpillar (*Pisina arenosella*) periodically causes severe proportions in coastal, water and other areas in the vicinity of water bodies. The caterpillars, hiding in the galleries on the lower side of leaves, feed on the mesophyll containing parenchymatous tissues. Damage to the leaves reduces the photosynthetic efficiency of the palm and reflects in the yield.

Biological control by the release of specific parasitoids is the major component in the IPM schedule recommended for combating the pest. Systematic adoption of this technique can achieve about 85-90% control of the pest in the field. Among the parasitoids used for field release, the gregarious larval ectoparasitoid, *Goniozus nephantidis* is one of the most promising agents. The parasite attacks the caterpillar and starts laying eggs. The elongate eggs are glued on the sides of the host. 10 to 20 eggs are laid on a caterpillar. Grubs hatch in about 36 hours and begin to feed on the body of the host. Attributes such as their searching ability, capacity to emerge in summer when the pest is at its peak, and production of a high proportion of females make it very effective. The success of a control programme is also dependent on the easy availability of the parasitoid for regular augmentative release.

Fourth or early sixth instar caterpillars are the ideal host stage for the bethyloid parasitoid. *Goniozus nephantidis* can be mass multiplied in the laboratory on the alternate host, the

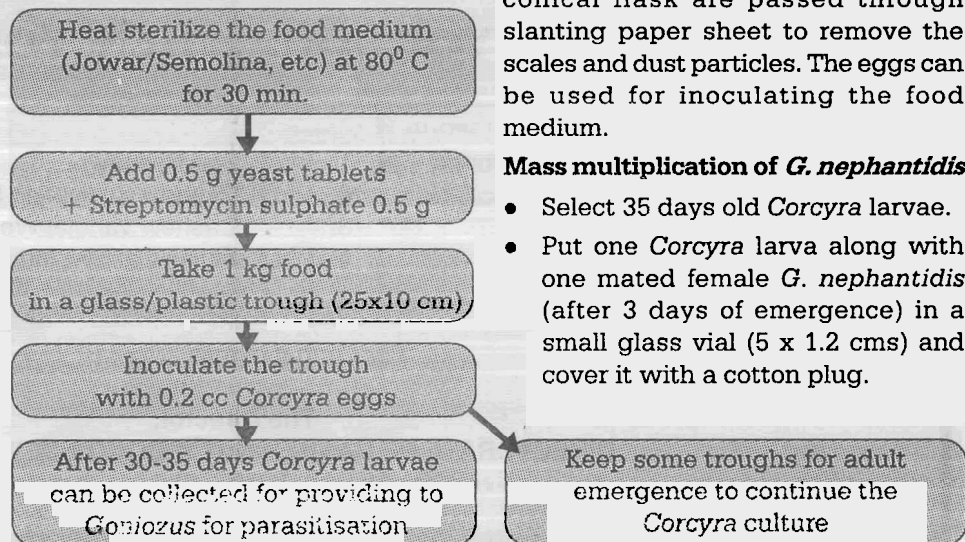

rice moth larva (*Corcyra cephalonica*) also. Egg to adult period of the parasitoid is completed in 10-14 days. Adult has up to three cycles of oviposition and brood care. Eggs laid by unmated females on host produce only males. Hence mated females are to be used

for mass multiplication of the parasitoid.

### *Corcyra* culture maintenance

*Corcyra* can be maintained in the laboratory on semolina (sooji) / wheat / pearl millet / jowar, etc. The most economic food medium can be selected depending upon the local availability

### Steps in the *Corcyra* culture maintenance

*Goniozus nephantidis*

and cost.

### *Corcyra* egg collection

Put the adult *Corcyra* moths in a cylindrical plastic jar (15 x 12 cms), the bottom portion of which is removed and replaced with a nylon mesh. Cover the top part also with the nylon mesh. Keep the jar over a funnel, the tail portion of which is introduced to a conical flask. The eggs collected in the conical flask are passed through slanting paper sheet to remove the scales and dust particles. The eggs can be used for inoculating the food medium.

### Mass multiplication of *G. nephantidis*

- Select 35 days old *Corcyra* larvae.
- Put one *Corcyra* larva along with one mated female *G. nephantidis* (after 3 days of emergence) in a small glass vial (5 x 1.2 cms) and cover it with a cotton plug.

Goniozus nephantidis larvae developing on Corcyra

Cocoons of G. nephantidis

- Keep the inoculated vial for 3-6 days for egg laying in a tray.  
Collect the larvae of the host with eggs of *G. nephantidis* from all the vials and transfer them onto a tissue paper (20 *Corcyra*/paper).
- Cover it with a net.
- Keep this under ordinary table lamp in a plastic tray on a pad of cotton.
- Precaution should be taken to avoid

- the attack of lizards, ants, rats, etc.
- After 3 days in light, remove all damaged / unwanted larval parts and clean the cocoons of *Gonizus*.
- Transfer one such paper containing cocoons to a test tube (15 x 2.5 cms) provided with honey soaked in cotton or honey droplets on wax-coated paper.
- The adults of *Goniozus nephantidis* emerge from cocoons in another 3-5

- days. There will be 150-200 *Goniozus* per test tube.
- After 3 days of emergence they can be released in the field as per norms or can be used for further multiplication.
- After rearing continuously for 4 generations on *Corcyra* larvae *Opisina* (the natural host larvae) must be provided as host in order to maintain the parasitic potential.

## THE CASHEWNUT!

A WONDER NUT OF NATURE

HEALTHY YOU ARE WHEN YOU CONSUME IT.  
WEALTHY YOU ARE WHEN YOU GROW IT.
